\textbf{Abstract:} We present a Two-Higgs-Doublet Model in which the structure of the quark Yukawa sector is governed by three spurions breaking the flavour symmetries. The model naturally suppresses FCNC amplitudes in the down-type sector, but permits sizable FCNC couplings in the up sector. We calculate the branching ratio of \( B_s \rightarrow \mu^+\mu^- \) to leading and next-to-leading order of QCD for the case with FCNC couplings of the heavy neutral Higgs bosons to top and charm quarks and verify that all counterterms follow the pattern dictated by the spurion expansion of the Yukawa matrices. We find correlations between \( B_s \rightarrow \mu^+\mu^- \), \( b \rightarrow s\gamma \), and the Higgs masses. The \( B_s - \bar{B}_s \) mixing amplitude is naturally suppressed in the model but can probe a portion of the parameter space with very heavy Higgs bosons.
1 Introduction

Two-Higgs-Doublet models (2HDMs) [1, 2] are a popular extension of the Standard Model (SM) due to their relative simplicity, involving no additional particles apart from a second Higgs doublet. Moreover, a strong motivation to study 2HDMs also comes from theories in which a second Higgs doublet is required due to symmetry arguments, e.g. axion models in the context of the strong CP puzzle [3–5] or minimal supersymmetry [6]. 2HDMs differ in the structure of Higgs-fermion Yukawa couplings. The historically most favoured variant is the so-called type-II 2HDM in which up- and down-type quarks couple to separate Higgs doublets exclusively. In most of the 2HDMs, flavour-changing neutral current processes such as the decay $B_s \rightarrow \mu^+\mu^-$ are loop-suppressed and therefore small masses of the additional Higgs bosons are in principle possible, an appealing feature during the early LHC searches. A general 2HDM exhibits, however, a much richer Yukawa structure [7, 8], in which flavour-changing neutral Higgs-boson couplings are possible, in case quarks couple to multiple Higgs doublets at the same time.
In this paper, we will consider the rare decay $B_s \rightarrow \mu^+ \mu^-$ in the context of a 2HDM with more general Yukawa couplings. The model under consideration will feature flavour-changing up-type Yukawa couplings of the additional neutral Higgs bosons, most notably a charm-top transition which may eliminate the Cabibbo-Kobayashi-Maskawa (CKM) suppression that is present in both the SM and the 2HDM type-II models. We put special emphasis on the leading corrections for large values of $\tan \beta$.

The outline of the paper is as follows: In section 2, we will introduce the effective operators contributing to the low-energy weak $B_s \rightarrow \mu^+ \mu^-$ decay. The Yukawa and Higgs sectors of the 2HDM are presented in section 3, while section 4 is dedicated to a short description of the computational setup used for the evaluation Feynman diagrams. The limiting case of the type-II 2HDM is introduced in section 5, with the additional contributions from flavour-changing neutral-Higgs Yukawa couplings being presented in section 6. Finally, we will discuss the phenomenology of such models in section 7, before summarizing in section 8.

2 The decay $B_s \rightarrow \mu^+ \mu^-$

The typical momentum scale for $B_s$ decays is of order $M_{B_s}$ or smaller, so that weak $B_s$ decays can be described by an effective theory in which the heavy $W, Z$ bosons, the top quark, and the Higgs bosons of the 2HDM are integrated out. The resulting $|\Delta B| = 1$ Hamiltonian $H_{\text{eff}}$ describes the interactions mediated by these heavy particles in terms of dimension-6 operators changing the beauty quantum number $B$ by one unit. The piece of $H_{\text{eff}}$ relevant for $B_s \rightarrow \mu^+ \mu^-$ reads

$$H_{\text{eff}} = N \sum_{i=A,S,P} (C_i Q_i + C'_i Q'_i). \quad (2.1)$$

The operators in Eq. (2.1) are

$$Q_A = (\bar{b} \gamma_\mu P_L s) (\bar{\mu} \gamma^\mu \gamma_5 \mu), \quad Q'_A = (\bar{b} \gamma_\mu P_R s) (\bar{\mu} \gamma^\mu \gamma_5 \mu),$$

$$Q_S = (\bar{b} P_L s) (\bar{\mu} \mu), \quad Q'_S = (\bar{b} P_R s) (\bar{\mu} \mu),$$

$$Q_P = (\bar{b} P_L s) (\bar{\mu} \gamma_5 \mu), \quad Q'_P = (\bar{b} P_R s) (\bar{\mu} \gamma_5 \mu), \quad (2.2)$$

and are multiplied with their respective Wilson coefficients $C_A, \ldots, C'_P$, which contain the dependence on the heavy masses. The normalisation factor in Eq. (2.1) is

$$N = \frac{G_F^2 M_W^2}{\pi^2} V_{ts} V_{tb}^* = \frac{G_F \alpha_{\text{em}} (\mu)}{\sqrt{2} \pi \sin^2 \theta_w} V_{ts} V_{tb}^*, \quad (2.3)$$

which complies with the conventions of Ref. [9]. The second “=” sign only holds to lowest order in the electroweak interaction, while in higher orders the relation between the Fermi constant $G_F$ and the electromagnetic coupling $\alpha_{\text{em}} = e^2/(4\pi)$, the weak mixing angle $\theta_w$ and the $W$ mass $M_W$ is modified. Electroweak corrections have been calculated in Ref. [10] and e.g. remove the ambiguities related to the choice of the renormalisation scheme for these parameters; in the second version for $N$ in Eq. (2.3) this issue also includes the choice of
the scale in the running $\alpha_{em}$. We choose the first definition $N \propto G_F^2$ in this paper, for which the electroweak corrections to the SM contribution to $C_A$ are as small as $-2.4\%$ [10].

We introduce the perturbative expansion of the $C_i$ as

$$C_i = C_i^{(0)} + \left(\frac{\alpha_s}{4\pi}\right) C_i^{(1)} + \ldots,$$

(2.4)

where $C_i^{(0)}$ denotes the leading order (LO), arising in the SM from one-loop electroweak diagrams. $C_i^{(1)}$ comprises the next-to-leading order (NLO) QCD corrections. In the SM only $C_A$ is relevant, $C_A'$ is suppressed w.r.t. $C_A$ by the ratio $m_b m_s/M_W^2$ involving strange and bottom masses $m_{(s,b)}$ and $C_i^{(0)}$ receive additional suppression factors of $M_{B_s}/M_W^2$.

The leading contributions $C_i^{(1)}$ arise from one-loop electroweak diagrams at order $G_F^2$ in the SM, hence the branching ratio is rather small.

The average time-integrated branching ratio is given by [11, 12]

$$\mathcal{B}(B_s \to \mu^+ \mu^-) = |N|^2 \frac{M_{B_s}^2 f_{B_s}^2 \beta}{8\pi^3 s} \left[ r (C_A - C_A') - u (C_P - C_P') \right]^2 F_P + |u \beta (C_S - C_S')|^2 F_S,$$

(2.5)

with dimensionless quantities

$$r = \frac{2m_\mu}{M_{B_s}}, \quad \beta = \sqrt{1 - r^2}, \quad u = \frac{M_{B_s}}{m_b + m_s}.$$

(2.6)

Here, $\Gamma_R$ ($\Gamma_L$) denotes the decay width of the heavier (lighter) $B_s$ mass eigenstate, and the factors $F_P$ and $F_S$ account for the mixing of the $B_s - \bar{B}_s$ system, given by

$$F_P = 1 - \frac{\Gamma_R - \Gamma_L}{\Gamma_L} \sin^2 \left[ \arg \left( r (C_A - C_A') - u (C_P - C_P') \right) \right],$$

$$F_S = 1 - \frac{\Gamma_R - \Gamma_L}{\Gamma_L} \cos^2 \left[ \arg \left( C_A' - C_S \right) \right]$$

(2.7)

in the absence of significant CP-violating New Physics contributions to the $B_s - \bar{B}_s$ mixing amplitude. In writing Eq. (2.5), we have used the pseudoscalar decay constant $f_{B_s}$ to rewrite the operator matrix elements as

$$\langle 0 | \bar{b} \gamma_\mu \gamma_5 s | B_s(p) \rangle = ip_\mu f_{B_s},$$

$$\langle 0 | \bar{b} \gamma_5 s | B_s(p) \rangle = -i f_{B_s} \frac{M_{B_s}^2}{m_b + m_s},$$

(2.8)

where the second equation follows from the first one by use of the Dirac equation.

3 2HDM with suppressed down-type FCNC couplings

3.1 General Yukawa sector

The Yukawa Lagrangian of the general (“type III”) 2HDM reads

$$L_Y = -\bar{Q}_f \left[ \bar{Y}_f^d H_d + \bar{\tau}_f^d H_u \right] d_R^f - \bar{Q}_f' \left[ \bar{Y}_f'^u \epsilon H_u^* + \bar{\tau}_f'^u \epsilon H_d^* \right] u_R^f + h.c.$$

$$\equiv -\bar{Q}_f \left[ \bar{Y}_f^d H_d + \bar{\tau}_f^d H_u \right] d_R^f - \bar{Q}_f' \left[ \bar{Y}_f'^u \epsilon H_u^* + \bar{\tau}_f'^u \epsilon H_d^* \right] u_R^f + h.c.$$

(3.1)
with
\[ H_{u,d} = \begin{pmatrix} H^+_u \\ H^0_u \\ H^0_{u,d} \end{pmatrix}, \quad \epsilon H^*_u,d = \begin{pmatrix} H^0_{u,d} \\ -H^{0*}_{u,d} \end{pmatrix} \] (3.2)
and
\[ Q'_f = \begin{pmatrix} u'_{fL} \\ d'_{fL} \end{pmatrix}. \] (3.3)

The subscripts \( f,i = 1,2,3 \) label the generations, e.g. \( u'_{3L} = t'_{3L} \). The notation in Eq. (3.1) follows Ref. [8], except that our \( H^d_d \) corresponds to \(-\epsilon H^d_d^* \) of that paper.

The vacuum expectation values (vevs) and related quantities are
\[ \langle H^0_u \rangle = v_u = v \sin \beta, \quad \langle H^0_d \rangle = v_d = v \cos \beta, \]
\[ \tan \beta := \frac{v_u}{v_d}, \quad v := \sqrt{v_u^2 + v_d^2} = 174 \text{ GeV}. \] (3.4)

The quark mass matrices are
\[ M^d = Y^d v \cos \beta + \epsilon^d v \sin \beta, \quad M^u = Y^u v \sin \beta + \epsilon^u v \cos \beta, \] (3.5)
which we diagonalise in the usual way:
\[ u'_{L,R} = S^u_{L,R} u_{L,R}, \quad d'_{L,R} = S^d_{L,R} d_{L,R}, \]
\[ S^d_{L} M^d S^d_{R} = \hat{M}^d = \begin{pmatrix} m_d & 0 & 0 \\ 0 & m_s & 0 \\ 0 & 0 & m_b \end{pmatrix}, \quad S^{u*}_{L} M^u S^{u*}_{R} = \hat{M}^u = \begin{pmatrix} m_u & 0 & 0 \\ 0 & m_c & 0 \\ 0 & 0 & m_t \end{pmatrix}, \] (3.6)
with the unprimed fields corresponding to quark mass eigenstates. The gauge sector of the 2HDM is invariant under independent unitary rotations of the fields \( Q', d'_R, \) and \( u'_R \) in flavour space. We use Eq. (3.6) and choose
\[ Q' = S^d_{L} Q \] (3.8)
and find \( L_Y \) in the so-called down basis:
\[ L_Y \equiv -Q \left[ Y^d H_d + \epsilon^d H_u \right] d_R - Q \left[ Y^u \epsilon H^*_u + \epsilon^u \epsilon H^*_d \right] u_R + h.c. \] (3.9)
with the appropriately transformed Yukawa matrices
\[ Y^{u,d} = S^{d\dagger}_{L} Y^{u,d} S^{u,d}_{R}, \quad \epsilon^{u,d} = S^{d\dagger}_{L} \epsilon^{u,d} S^{u,d}_{R} \] (3.10)
and the CKM matrix
\[ V = S^{u\dagger}_{L} S^{d}_{L}. \] (3.11)

The Yukawa Lagrangian \( L_Y \) in Eq. (3.9) is manifestly \( SU(2) \) invariant, with the \( SU(2) \) doublet
\[ Q = S^d_{L} Q' = \begin{pmatrix} V^t u_L \\ d_L \end{pmatrix}. \]
Eq. (3.9) is our starting point; the Yukawa matrices are related to the diagonal mass matrices as

\[
\frac{\hat{M}_d}{v} = Y^d \cos \beta + \epsilon^d \sin \beta, \quad \frac{\hat{M}_u}{v} = V (Y^u \sin \beta + \epsilon^u \cos \beta) .
\] (3.12)

Non-vanishing off-diagonal entries of \(Y^d,u\), \(\epsilon^d,u\) give rise to FCNC couplings of the neutral components of the Higgs doublets.

In a general 2HDM the quantity tan \(\beta\) has no physical meaning: One can arbitrarily rotate \((H_u, H_d)\) in Eq. (3.1) leading to a Lagrangian of the same form (yet with different Yukawa matrices) and the rotation angle will add to \(\beta\). The situation is different in variants of the 2HDM in which \(H_u\) and \(H_d\) are distinguished by quantum numbers which forbid such rotations of \((H_u, H_d)\). Prominent examples are the 2HDM of type I and II, in which two out of the four Yukawa matrices in Eqs. (3.1) and (3.9) are absent. The type-I model corresponds to \(\epsilon^d = Y^u = 0\). The type-II model is instead found for \(\epsilon^d = \epsilon^u = 0\).

The doublets \(\phi_{SM}, \phi_{new}\) of the Higgs basis \([13–15]\) are defined by a rotation of the two doublets \(H_u, H_d\) by the angle \(\beta\) such that \(\phi_{new}\) has no vev:

\[
\begin{pmatrix}
\phi_{new} \\
\phi_{SM}
\end{pmatrix} =
\begin{pmatrix}
\cos \beta & -\sin \beta \\
\sin \beta & \cos \beta
\end{pmatrix}
\begin{pmatrix}
H_u \\
H_d
\end{pmatrix} .
\] (3.13)

One has

\[
\phi_{SM} = \begin{pmatrix}
G^+ \\
\phi^0 + iG^0
\end{pmatrix} , \quad \phi_{new} = \begin{pmatrix}
H^+ \\
\phi^0 + iA^0
\end{pmatrix} .
\] (3.14)

Next we use Eq. (3.13) to express \(L_Y\) in terms of \(\phi_{SM}\) and \(\phi_{new}\):

\[
L_Y = \bar{Q} \left[ -Y^d \cos \beta - \epsilon^d \sin \beta \right] \phi_{SM} d_R + \bar{Q} \left[ Y^d \sin \beta - \epsilon^d \cos \beta \right] \phi_{new} d_R
\]
\[
+ \bar{Q} V^\dagger \left[ -Y^u \sin \beta - \epsilon^u \cos \beta \right] \epsilon \phi_{SM}^* u_R + \bar{Q} V^\dagger \left[ -Y^u \cos \beta + \epsilon^u \sin \beta \right] \epsilon \phi_{new}^* u_R + h.c.
\] (3.15)

By using Eq. (3.5) to eliminate \(Y^u\) and \(Y^d\) one can write the couplings to physical charged and neutral Higgs bosons in Eq. (3.15) as

\[
L_Y^{\text{phys}} = - \bar{u}_L \left[ \frac{\hat{M}^u}{v} \cot \beta + g^u \right] u_R \phi^0 \left[ \frac{d_R \phi^0 - iA^0}{\sqrt{2}} \right] + \bar{d}_L \left[ \frac{\hat{M}^d}{v} \tan \beta + g^d \right] d_R \frac{\phi^0 + iA^0}{\sqrt{2}}
\]
\[
+ \bar{u}_L V \left[ \frac{\hat{M}^d}{v} \tan \beta + g^d \right] d_R H^+ + \bar{d}_L V^\dagger \left[ \frac{\hat{M}^u}{v} \cot \beta + g^u \right] u_R H^-
\]
\[
- \bar{d}_L \frac{\hat{M}^d}{v} d_R \left( v + \frac{\phi^0}{\sqrt{2}} \right) - \bar{u}_L \frac{\hat{M}^u}{v} u_R \left( v + \frac{\phi^0}{\sqrt{2}} \right) + h.c.
\] (3.16)

with the matrices [8]

\[
g^d = -\epsilon^d \sin \beta (\tan \beta + \cot \beta), \quad g^u = -\epsilon^u \cos \beta (\tan \beta + \cot \beta) .
\] (3.17)
The non-diagonal matrices $g^d$ and $g^u$ characterise the deviations from the popular type-II 2HDM (for which $g^d = g^u = 0$) and can induce flavour-changing couplings of neutral Higgs bosons. Note that the type-I model is also included in the formalism and recovered by using Eq. (3.5) with $Y^u = 0$ in the expression for $g^d$. For our loop calculation and the phenomenological analysis it is advantageous to work with $g^{d,u}$ rather than $\epsilon^{d,u}$, especially for the definition of the renormalisation prescriptions. We write $g_{ij}^d = g_{di}^d e_j$, where $d_i$ is the $i$-th down-type quark flavor, $i = 1, 2, 3$, and similarly for $g^u$.

We are interested in 2HDM scenarios in which current and forthcoming measurements by LHCb and CMS can find deviations in $B(B_s \to \mu^+\mu^-)$ from the SM prediction. This consideration guides us to lepton Yukawa couplings of the type-II form,

$$L_Y = +\bar{l}_L \left( \frac{\hat{M}^l}{v} \sin(\beta - \alpha) \, \cos(\beta - \alpha) \, 0 \right) l_R \phi^0 + i A^0 \tan \beta l_R H^+ + h.c. \tag{3.18}$$

and large values of $\tan \beta$ to enhance the muon Yukawa coupling $Y_\mu = m_\mu/v \tan \beta$ over its SM value. $\hat{M}^l$ in Eq. (3.18) denotes the diagonal mass matrix of the charged leptons.

We restrict ourselves to the CP-conserving Higgs potential, in which diagrams involving $A^0$ contribute to the Wilson coefficient $C_P$, while diagrams with the CP-even neutral Higgs states contribute to $C_S$. The two Higgs bosons $\phi^0$ and $\phi'^0$ are in general not mass eigenstates. The latter are given by

$$\begin{pmatrix} h^0 \\ R^0 \\ A^0 \end{pmatrix} = \begin{pmatrix} \sin(\beta - \alpha) & \cos(\beta - \alpha) & 0 \\ \cos(\beta - \alpha) & -\sin(\beta - \alpha) & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \phi^0 \\ \phi'^0 \\ A^0 \end{pmatrix}. \tag{3.19}$$

The angle $\alpha$ is an a priori arbitrary parameter of the theory that serves to diagonalise the mass matrix of neutral Higgs bosons.

### 3.2 Spurion expansion

The 2HDM of type I and II (and their variants with modified lepton couplings) invoke (softly broken) $Z_2$ symmetries to forbid FCNC couplings of the neutral Higgs bosons. This was motivated by the wish to find non-standard Higgs bosons at modern colliders, because for generic values of the Yukawa matrices in Eq. (3.9) constraints from FCNC processes like meson-antimeson mixing push these masses to values outside the reach of LEP, Tevatron, and LHC. With the absence of discoveries of non-standard Higgs bosons this line of arguments loses its appeal and the consideration of more general Yukawa sectors is in order.

The type-II model is the most studied variant of the 2HDM for two reasons: Firstly, it constitutes the tree-level Higgs sector of the Minimal Supersymmetric Standard Model (MSSM), in which the holomorphy of the superpotential enforces $\epsilon^{u,d} = 0$. Secondly, the type-II model is phenomenologically especially interesting, because in this model FCNC processes are sensitive to loop effects of the charged Higgs boson. A prominent example of the latter feature is the branching ratio $B(B \to s\gamma)$, which sets a stringent bound on the charged-Higgs mass [16]. The type-II 2HDM further permits the possibility of
large down-type Yukawa couplings, a scenario motivated by the possibility of bottom-top Yukawa unification. Such large-$\tan\beta$ scenarios are efficiently constrained by $B(B_s \to \mu^+\mu^-)$ \cite{9, 17, 18} and we will come back to this topic in section 5. Concerning the first above-mentioned motivation, the Higgs sector of the MSSM is really richer than that of the type-II 2HDM: In the limit of infinitely heavy superpartners one encounters non-decoupling loop-induced Yukawa matrices $\epsilon^{u,d}$, an effect caused by the supersymmetry-breaking terms \cite{19–21}. Despite the loop suppression large effects are possible in FCNC processes with down-type quarks which involve the product $\epsilon^d \tan\beta$ \cite{22–27} with huge impact on $B(B_s \to \mu^+\mu^-)$ \cite{22–25, 28}.

The phenomenological constraints from meson-antimeson mixing and rare (semi-)leptonic decays place severe bounds on the off-diagonal elements of $\epsilon^d$, while those of $\epsilon^u$ are essentially unconstrained except for $\epsilon^u_{12}$ and $\epsilon^u_{21}$. This situation calls for a variant of the 2HDM in which $Y^{u,d}$ and $\epsilon^u$ are arbitrary, while $\epsilon^d$ is suppressed. A strong motivation for such a model is the possibility of spontaneous CP violation, implemented through a Higgs potential developing complex vevs and real Yukawa matrices. Spontaneous CP violation is not possible with a 2HDM of type I or II, but requires at least three out of the four matrices in Eq. (3.9) to be non-zero. Avoiding fine-tuning implies that the better part of the needed effect stems from $\epsilon^u$, while $\epsilon^d$ can be neglected \cite{29}. However, in such a model, the mixing of the neutral Higgs fields is different from Eq. (3.19) and instead involves all three fields. Yet for the CP-conserving observables considered in this paper this feature is of minor relevance. The 2HDM scenario with sizable $Y^{u,d}$ and $\epsilon^u$ has the appealing feature that it simultaneously permits both measurable effects in FCNC processes and sufficiently light masses of the non-standard Higgs particles enabling their discovery at the LHC.

Setting $\epsilon^d$ naively to zero leads to a non-renormalisable model, because there are UV-divergent loops involving up-type quarks with $Y^{u,d}$ and $\epsilon^u$ couplings, which require counterterms proportional to elements of $\epsilon^d$. Whenever one seeks to constrain the elements $g^{u}_{jk}$ of Eq. (3.16) from FCNC transitions of down-type quarks, one must foresee such a counterterm to find a meaningful prediction. For example, $B_s \to \mu^+\mu^-$ is a $b \to s$ transition constraining $g_{ct}$ and the corresponding loop contribution requires a counterterm for $g_{sb}$. The minimal renormalisable theory is found by invoking flavour symmetries and systematically expanding in terms of the spurions breaking these symmetries \cite{30, 31}. The 2HDM gauge sector is invariant under unitary rotations $Q \to U_Q Q$, $d_R \to U_d d_R$, $u_R \to U_u u_R$ in flavour space with $(U_Q, U_d, U_u) \in SU(3)^3$ and the Yukawa sector is formally invariant under this flavour symmetry if one transforms the matrices in Eq. (3.9) as

$$Y^{u,d} \to U_Q Y^{u,d} U_{u,d}^\dagger, \quad \epsilon^{u,d} \to U_Q \epsilon^{u,d} U_{u,d}^\dagger.$$  \hspace{1cm} (3.20)

We propose to categorise the classes of renormalisable 2HDM in terms of the spurions breaking the $SU(3)^3$ flavour symmetry of the quark sector.\footnote{The generalisation to the lepton sector is straightforward, but not relevant for the calculations in this paper.} The minimal choice are two spurions, with just two physically distinct possibilities. Both comply with the definition of minimal flavour violation (MFV) as defined in Ref. \cite{31}. The first possibility is to take $Y^{u,d}$
as spurions and express the other two Yukawa matrices as $e^{u,d} = P_{u,d}(Y_u Y_u^\dagger, Y_d Y_d^\dagger) Y^{u,d}$, where $P_u$ and $P_d$ are polynomials. This variant is discussed in Ref. [31] and amounts to a generalisation of the 2HDM of type II. It also constitutes a renormalisable extension of the aligned 2HDM of Ref. [32, 33], in which $P_{u,d}$ are constants. If the 2HDM is the low-energy limit of a more fundamental theory obeying the considered two-sporion symmetry-breaking pattern, the latter will naturally induce $e^{u,d}$ in the described way as well. An example for such a UV theory is the MSSM with a flavour-blind supersymmetry breaking mechanism (such as gauge mediation). The second possibility is to choose $Y_d$, $\epsilon^u$ as spurions, leading to a generalisation of the type-I 2HDM.

There are two possibilities for a 2HDM with three spurions, which can be taken as $Y_u, Y_d$ plus either $\epsilon^u$ or $\epsilon^d$. The first possibility is the phenomenologically interesting one and studied in this paper. The expansion up to third order reads

$$e^d = c Y^d + c_{11} Y^d Y^d \dagger Y^d + b_{11} \epsilon^u \epsilon^u \dagger Y^d + b_{12} \epsilon^u Y^u \dagger Y^d + b_{21} \epsilon^u Y^u \dagger Y^d + b_{22} Y^u Y^u \dagger Y^d$$

(3.21)

with complex coefficients $c, \ldots, b_{22}$.

Concerning Eq. (3.21) several comments are in order:

- The spurion expansion is only meaningful, if the contributions to the off-diagonal elements of $e^d$ from higher electroweak orders (with five or more Yukawa matrices) are small, so that they can be neglected. A sufficient condition for this is realised in scenarios in which $c_1, \ldots, b_{22}$ are induced by one-loop contributions in either the UV completion or the 2HDM, while terms with $(2n + 1)$ spurions are only generated at $n$-loop order and beyond. We consider this scenario throughout this paper. Additional QCD corrections (e.g. an extra loop with a gluon) comply with the pattern in Eq. (3.21), i.e. QCD renormalises the coefficients, but does not induce new ones.

- By rotating $\left( H_u, H_d \right)$ in Eq. (3.9) one can eliminate $c$ in Eq. (3.21). But in general radiative corrections bring this term back and a counterterm to $c$ is needed, unless one corrects the rotation in each order of perturbation theory. It is therefore advisable to keep $c$ in Eq. (3.21); we treat it as a perturbative quantity with $c = 0$ at tree level.

- The decay $B_s \to \mu^+\mu^-$ involves the FCNC vertex $\overline{Q}_j \gamma \gamma R_k H_d$ with $(j,k) = (2,3)$. The dominant one-loop vertex diagram involves an internal $H_d$ line and the product $Y^d Y^d \dagger Y^d$ or $\epsilon^u \epsilon^u \dagger Y^d$ stemming from the three $H_d$ Yukawa couplings. The UV divergences can be cancelled by counterterms to $c_{11}$ and $b_{11}$.

- With Eq. (3.12) we can trade $Y^{u,d}$ in Eq. (3.21) for the quark masses and CKM elements. Compared to the SM we find 14 additional complex parameters, the 9 entries of $e^u$ and $c_{11}, \ldots, b_{22}$. Yet it is much more convenient to express observables

---

2A different application of Eq. (3.21), in which $c_{11}, \ldots, b_{22} = O(1)$ is allowed, is the case that $Y^u$ and $e^u$ are almost aligned, so that Eq. (3.12) means small off-diagonal matrix elements of these matrices in the chosen basis. Since $Y^u_{33}, \epsilon^u_{33} = O(1)$ and further $Y^u_{33} = O(1)$ is possible, some terms with five spurions must be added to Eq. (3.21), just as in the MFV case of Ref. [31].
in terms of $g_{jk}^u$ of Eq. (3.16) instead of $\epsilon_{jk}^u$ and then use Eqs. (3.17) and (3.21) (with Eq. (3.12)) to calculate the $g_{jk}^d$ in terms of the coefficients of the spurion expansion. While this procedure is needed in a global analysis of all available data —which is beyond the scope of this paper—, the study of $b \to s$ transitions alone will simply involve $g_{ct}$ and $g_{tt}$.

In a practical calculation it is cumbersome to implement the renormalisation procedure in the described way, by providing counterterms to $\epsilon_{jk}^u$ and $c, \ldots, b_{22}$. Instead, it is much easier to renormalise the $g_{jk}^{u,d}$. If one renormalises all $g_{jk}^{u,d}$ in the $\overline{\text{MS}}$ scheme, one automatically complies with SU(2)$\times$U(1) gauge symmetry. Therefore it is sufficient to choose the $g_{jk}^d$ in such a way that Eq. (3.21) is obeyed at tree level. In our calculation we will only need a counterterm to $g_{sb}$ (in addition to the usual QCD counterterms for the SM parameters), if $m_s$ is set to zero. If $m_s$ is kept, one finds primed Wilson coefficients which require a counterterm to $g_{bs}$.

4 Computational setup

In this section, we describe the chain of programs used to generate and evaluate the corresponding Feynman diagrams at leading and next-to-leading order. We use FeynRules with the Universal FeynRules Output (UFO) \cite{34-36} to obtain Feynman rules for the model. The output is processed by tapir \cite{37} into a Lagrangian file, which is used with qgraf \cite{38} in order to generate all Feynman diagrams.

We compute the one-loop diagrams for general electroweak gauge parameters for the $W$ and $Z$ bosons and check that they drop out in the final result. This is a welcome check for the conversion from UFO to qgraf and tapir. If diagrams with all different quark flavours are explicitly calculated, we have at one-loop level $< O(100)$ Feynman diagrams in the SM,\cite{3} and an additional $O(300)$ diagrams from contributions with at least one non-SM Higgs boson, most of which are Higgs-penguin diagrams.

At two loop-order, we perform the calculation in the Feynman gauge for the $W$ and $Z$ bosons. The diagrams are then converted with the help of tapir into FORM \cite{39} code using Feynman rule definitions that were also produced in the conversion from UFO to the qgraf Lagrangian file. The individual expressions for the diagrams are mapped onto integral families using exp \cite{40, 41} and a custom FORM setup is used to perform the remaining computational steps. Since the Wilson coefficients are independent of the momenta of the external particles, we set the latter to zero, so that only vacuum integrals need to be computed. (An exception are diagrams with an FCNC self-energy in an external leg, which are calculated with on-shell $b$ quark and $m_b \neq 0$ before the subsequent limit $m_b \to 0$ is taken.) We use a FORM implementation of the algorithm presented in Ref. \cite{42}, see Ref. \cite{43}.
\[ \bar{b} s \mu^+ \bar{b} s \mu^- \nu_\mu \mu^- \bar{b} s \mu^+ \bar{b} s \mu^- \nu_\mu \mu^- \]

Figure 1. Sample diagrams contributing to \( C_A \) at leading and next-to-leading order in the SM.

5 The decay \( B_s \rightarrow \mu^+ \mu^- \) in the Two-Higgs-Doublet Model of type-II

In the SM next-to-leading order corrections are available from Refs. [44–48] and higher order QCD and electroweak corrections have been computed in Refs. [9, 10, 18, 49, 50]. Next-to-leading corrections in the type-II 2HDM have been computed in Refs. [17, 51–53], which we have reproduced for the present paper, also as a check of the automated setup. The result can be expressed in terms of dimensionless mass ratios of the top quark, \( W \) boson and charged Higgs boson masses,

\[ x_t = \frac{m_t^2}{M_W^2}, \quad r_H = \frac{m_H^2}{M_{H^+}^2}. \] (5.1)

In the SM, only the Wilson coefficient \( C_A \) receives significant contributions from diagrams such as the ones depicted in Fig. 1. The Wilson coefficients \( C'_A, C_S, \ldots, C'_P \) are suppressed by powers of ratios of light (external) masses and \( M_W \). The leading SM contribution is, moreover, independent of the Yukawa couplings of all external particles, that is we can set

\[ m_l^2 (k^2 - M^2)^{-1} \]

and

\[ (k^2 - \xi M^2)^{-1} \]

respectively, and treat them as different diagrams; hence the large number of diagrams in the 1-loop calculation.

From the technical perspective, it is convenient to split the electroweak gauge bosons into two different "particles", with different propagator denominators \((k^2 - M^2)^{-1}\) and \((k^2 - \xi M^2)^{-1}\), respectively, and treat them as different diagrams; hence the large number of diagrams in the 1-loop calculation.
Figure 2. Sample two-loop Feynman diagrams contributing to the Wilson coefficients $C_{i}^{(0)} (H_{1,2})$ and $C_{j}^{(0)} (A^0)$. In the left diagram, only flavour-diagonal transitions $i = j$ are possible in the type-II 2HDM, while the more general 2HDM allows also for transitions with $i \neq j$, e.g. transitions from a charm quark into a top quark.

$m_b = m_s = m_\mu = 0$ for the contributions from $W$-box and $Z$-penguin diagrams. At leading and next-to-leading order they are given by

$$C_A^{W+Z,(0)} = \frac{x_t (x_t - 4)}{8 (x_t - 1)} + \frac{3 x_t^2 \log x_t}{8 (x_t - 1)^2},$$

$$C_A^{W+Z,(1)} = \frac{2x_t (2x_t^2 + 5x_t + 5)}{3 (x_t - 1)^2} - \frac{x_t (x_t^2 + 5x_t + 2) \log x_t}{(x_t - 1)^2} - \frac{x_t (x_t^2 + 2) \log (x_t - 1)^2 - \frac{6x_t^2 \log x_t}{(x_t - 1)^2} - \frac{m_t^2}{m_t^2},}$$

where the $Z$-penguin contributions include the flavour-changing quark self-energy diagrams required to make the penguin diagrams finite. Moreover, since charm and up quark masses can be neglected compared to $M_W$ and $m_t$, after summation over internal up-type quarks all contributions are proportional to the CKM factor $V_{ts} V_{tb}^*$ (contained in the normalisation factor $N$ defined in Eq. (2.3)) due to the unitarity of the CKM matrix.

In the type-II Two-Higgs-Doublet model, the leading terms are given by $O (\tan^2 \beta)$ contributions to $C_{i}^{(0)}$ and $C_{j}^{(0)}$, arising from penguin diagrams with a neutral Higgs boson, see e.g. Fig. 2, and the $W^+ - H^+$ box diagram. The Higgs-penguin contributions to $C_S$ are given by

$$C_{S}^{(0)} = - \frac{r_H x_t \log r_H}{4 (r_H - 1) (r_H - x_t)} - \frac{r_H x_t \log x_t}{4 (x_t - 1) (r_H - x_t)},$$

$$C_{S}^{(1)} = - \frac{r_H x_t \log r_H}{3 (x_t - 1) (r_H - x_t)} + \frac{2r_H x_t (3r_H - 7) \log r_H}{3 (x_t - 1)^2 (r_H - x_t)} - \frac{2r_H x_t (3r_H - 7) \log x_t}{3 (x_t - 1)^2 (r_H - x_t)} - 2 \log \left( \frac{\mu^2}{m_t^2} \right) \left( \frac{r_H x_t}{(r_H - 1) (x_t - 1)} + \frac{r_H x_t \log r_H}{(r_H - 1)^2 (r_H - x_t)} - \frac{r_H x_t \log r_H}{(r_H - 1)^2 (r_H - x_t)} \right) + \frac{2r_H x_t \log (1 - \frac{1}{x_t})}{r_H - x_t} - \frac{2r_H x_t \log (1 - \frac{1}{x_t})}{r_H - x_t},$$

$$+ \frac{2r_H x_t \log (1 - \frac{1}{x_t})}{r_H - x_t}.$$
where

\[ r_q = \frac{m_b m_q \tan^2 \beta}{M_W^2} \quad (5.6) \]

The Wilson coefficients for the right-handed operators \( C_{S,i}^{R,(i)} \) can be obtained by the replacement \( r_b \to r_s \) in Eqs. (5.4) and (5.5). Further contributions include terms of order \( m_b m_s m^2_\mu \tan^4 \beta / M_W^4 \) and \( m^2_\mu / M_W^4 \) entering the Wilson coefficients \( C'_A \) and \( C_A \), respectively, as well as \( O \left( m_b m_s \tan^2 \beta / M_W^2 \right) \) (in \( C'_A \)) and \( O \left( m^2_\mu \cot^2 \beta / M_W^2 \right) \) (in \( C_A \)) terms arising from Z-penguin diagrams with a charged Higgs boson. Box diagrams with a single charged Higgs boson also contribute to \( C_{S,P} \) (\( C'_{S,P} \)), with Wilson coefficients proportional to \( m_b \) (\( m_s \)). We do not explicitly list these contributions here; they can be found in Refs. [51–53]. With the exception of the doubly muon-mass suppressed \( H^+ - H^- \) box contributions to \( C_A \), we include all of these additional terms in our analysis. The feature that \( C_S \) and \( C_P \) are proportional to \( m_b \) while their primed counterparts are proportional to \( m_s \) holds beyond the type-II 2HDM in our more general 2HDM with three spurions because of \( \epsilon^d = P_{d} (e^a, Y^a, Y^d) Y^d \), entailing factors of \( m_{d_j} \) in Yukawa couplings of \( d_{jR} \). A rather remarkable feature of the type-II 2HDM is the fact that the leading terms in \( \tan \beta \) depend only on \( \tan \beta \) and the charged-Higgs boson mass \( M_{H^+} \), that is they are independent of the parameters of the neutral Higgs sector [17]. In the type-II 2HDM, the leading \( \tan^2 \beta \) contributions to the pseudoscalar and scalar Wilson coefficients satisfy the rather simple relation

\[ C_S = C_P, \quad C'_S = -C'_P. \quad (5.7) \]

In Fig. 3 we show the branching ratio \( B (B_s \to \mu^+ \mu^-) \) in the type-II 2HDM as a function of the charged Higgs boson mass. The horizontal gray, blue, and violet bands correspond to the experimental measurements of LHCb [57] and CMS [56] as well as the theory prediction [18], respectively, including 2\( \sigma \) uncertainties for the experimental values (cf. Table. 1). The theory prediction of Ref. [18] uses \( |V_{cb}| = 0.0424 \pm 0.0009 \), which is close to today’s value inferred from inclusive \( b \to c \ell \nu \) decays. If one uses \( |V_{cb}| = 0.03936 \pm 0.00068 \) from exclusive \( B \) decays [58] the central value of the theory prediction for \( 10^3 B (B_s \to \mu^+ \mu^-) \) drops from 3.65 to 3.15.

The coloured lines are predictions from the 2HDM for different values of \( \tan \beta \). It is interesting to note that for \( \tan \beta = 25 \) low values of \( M_{H^\pm} \) are required to reproduce the central value of the LHCb measurement. Recently it has been pointed out that LHC data still permit \( M_{H^\pm} \leq 400 \) GeV with couplings compatible with solutions of the \( b \to c \tau \nu \) flavour anomalies [59]. Charged-Higgs explanations of the latter have been found viable in Ref. [60, 61] and are invigorated by recent LHCb data on \( B \to D^{(s)} \tau \nu \) [62], see Refs. [63, 64]. Of course, in the limit \( M_{H^\pm} \to \infty \) all 2HDM curves approach the SM prediction. Note that in the type-II model there is a \( \tan \beta \)-independent 95\% C.L. lower bound on \( M_{H^\pm} \) in the range 570-800 GeV from \( B \to X_s \gamma \) [16]. This bound can be easily weakened with our model’s additional couplings discussed in the following section. While charged Higgs searches at the LHC are compatible with the quoted \( H^\pm \) masses [65], the lower bound on \( M_{H^\pm} \) inferred from the data on \( gg/b\bar{b} \to A^0 \to \tau^+ \tau^- \) searches is larger than 1 TeV [66] in
perturbed versions of the type-II 2HDM, but can be weakened if e.g. the $A^0$ coupling to $\tau$’s is modified w.r.t. to the type-II form in Eq. (3.18).

6 Additional contributions in a model with flavour-changing neutral Yukawa couplings

In a model with a Yukawa Lagrangian given by Eq. (3.16) there are additional tree-level contributions $b\bar{s} \to h^0(H^0,A^0) \to \mu^+\mu^-$ of order $\tan\beta$. A sample Feynman diagrams is shown in Fig. 4. At loop-level there are $O(\tan^3\beta)$ terms due to diagrams in which the neutral Higgs boson couples to the $b$ line. At LO these are diagrams with a FCNC self-energy and we also refer to them as self-energy diagrams at NLO, even if a gluon connects the FCNC loop with the $s$ quark as in the diagram on the right in Fig. 2. These $O(\tan^3\beta)$ terms occur because a $\tan\beta$-enhanced coupling in the self-energy diagrams is not cancelled by a factor $\cot\beta$ in the second charged-Higgs coupling, which is a distinguishing feature compared to the type-II model. If these self-energy diagrams involve a helicity flip of the internal fermion line, see Fig. 5, they come with a factor of $\tan\beta$ and are linear in the flavour-changing Yukawa matrix $\hat{g}^{u}$, which enters the result through the charged-Higgs coupling in the fourth term of Eq. (3.16). In fact, the dominant dependence on $g_{ct}$ stems from this source and not from diagrams in which a neutral Higgs boson couples to charm.
Figure 4. Tree-level diagrams with flavour-changing neutral Higgs couplings. The $b - s - H$ coupling is denoted by a dot on the vertex.

Figure 5. The loop-induced change of flavours $s \rightarrow b$ via a quark self-energy diagram. The helicity flip denoted by the cross ensures a factor of $\tan \beta$ and linearity in $\tilde{g}^u$.

and top in a vertex diagram, which have a factor of $\tan \beta$ less. Note that contributions from diagrams without helicity flip are either already included in the type-II model or quadratic in $\tilde{g}^u$ (and without the factor $\tan \beta$), and we will consequently neglect the latter in what follows.

6.1 Pseudoscalar Wilson coefficient $C_P$

At tree level the Wilson coefficient $C_P$ originating from the diagram in Fig. 4 with a virtual $A^0$ boson is given by

$$C_P^{(0),\text{tree}} = -\frac{\pi^2}{G_F^2 M_W^2 V_{tb} V_{ts}} \frac{m_t \tan \beta}{2v M_{A^0}^2} g_{sb} = -\frac{g_{sb}^*}{g_{bs}} C_P^{(0)}. \quad (6.1)$$

Since there is no loop-suppression, even small values of $g_{bs}$ and $g_{sb}^*$ can have significant impact on the branching ratio, but the spurion expansion in Eq. (3.21) naturally leads to (parametrically suppressed) small couplings. For convenience, let us define the linear combinations $g_{bs}^\pm = g_{bs} \pm g_{sb}^*$.

At one-loop order only the self-energy diagrams contain an enhancement factor $\tan^3 \beta$ whereas the vertex contributions contain at most a quadratic term. The one-loop self-energy contributions to $C_P$ and $C_P'$ are ultra-violet divergent. The corresponding counterterm is generated from Eq. (6.1) and is of the form

$$g_{bs}^{+0} = g_{bs}^+ + \delta_{A^0,bs} + \left(\frac{\alpha_s}{4 \pi}\right) \delta_{A^0,bs}^{(1)} + \cdots. \quad (6.2)$$
In the $\overline{\text{MS}}$ renormalisation scheme the one-loop contribution is given by

$$\delta_{A^0,sb}^{(0)} = -\frac{1}{\epsilon} \frac{\sqrt{2} G_F m_t \tan^2 \beta}{8\pi^2} \left[ m_s g_{ct} V_{ts} V_{tb}^* + (m_s g_{tt} V_{ts} + m_b g_{ct} V_{cs} + m_b g_{tt} V_{ts} ) V_{tb}^* \right]. \quad (6.3)$$

Here, the terms with $m_b$ renormalise the Wilson coefficient $C_P$, while the ones with $m_s$ renormalise the Wilson coefficient $C'_P$. The renormalised finite pseudoscalar Wilson coefficients read

$$C_P^{(0)} = C_P^{(0),\text{tree}} + \tilde{N} \frac{m_b}{M_A^2} \left( g_{ct}^* \frac{V_{cs}}{V_{ts}} + g_{tt}^* \right) \tilde{C}_P^{(0)},$$

$$C_P'^{(0)} = C_P'^{(0),\text{tree}} - \tilde{N} \frac{m_s}{M_A^2} \left( g_{ct}^* \frac{V_{cs}}{V_{tb}} + g_{tt}^* \right) \tilde{C}_P'^{(0)}, \quad (6.4)$$

with normalisation factor

$$\tilde{N} = \frac{m_t m_\mu \tan^2 \beta}{G_F \sqrt{2} M_W v} = \frac{g m_t m_\mu \tan^2 \beta}{2 G_F M_W^2}, \quad (6.5)$$

the weak coupling constant $g$, and

$$\tilde{C}_P^{(0)} = -\frac{1}{8} \left[ 1 + \log \left( \frac{\mu^2}{m_t^2} \right) - \log \frac{r_H}{r_H - 1} \right]. \quad (6.6)$$

At NLO in QCD (i.e. two-loop order), the counterterm required to obtain a finite result is given by

$$\delta_{A^0,sb}^{(1)} = -\frac{G_F m_t \tan^2 \beta}{\sqrt{2}\pi^2} \left[ m_s g_{ct} V_{ts} V_{cs}^* + (m_s g_{tt} V_{ts} + m_b g_{ct} V_{cs} + m_b g_{tt} V_{ts} ) V_{tb}^* \right]$$

$$\times \left[ \frac{1}{\epsilon^2} + \frac{4}{3\epsilon} \right]. \quad (6.7)$$

Note that in addition to the top quark mass $m_t$ also the flavour-changing Yukawa couplings are minimally renormalised. The two-loop contribution to the Wilson coefficients reads

$$C_P^{(1)} = \tilde{N} \frac{m_b}{M_A^2} \left( g_{ct}^* \frac{V_{cs}}{V_{ts}} + g_{tt}^* \right) \tilde{C}_P^{(1)},$$

$$C_P'^{(1)} = -\tilde{N} \frac{m_s}{M_A^2} \left( g_{ct}^* \frac{V_{cs}}{V_{ts}} + g_{tt}^* \right) \tilde{C}_P'^{(1)}, \quad (6.8)$$

with

$$\tilde{C}_P^{(1)} = -\frac{4(r_H - 2)}{3(r_H - 1)} + \frac{(3r_H - 7)(\log(r_H))}{3(r_H - 1)^2} + \left( 7 - 4r_H \right) \log \left( \frac{r_H}{r_H - 1} \right) \log \left( \frac{\mu^2}{m_t^2} \right)$$

$$- \frac{1}{2} \log^2 \left( \frac{\mu^2}{m_t^2} \right) + \text{Li}_2 \left( 1 - \frac{1}{r_H} \right). \quad (6.9)$$

### 6.2 Scalar Wilson coefficient $C_S$

The scalar Wilson coefficients receives contributions from both neutral CP-even Higgs mass eigenstates $h^0$ and $H^0$. At tree level, the diagrams with $h^0$ and $H^0$ give rise to the Wilson coefficients

$$C_S^{(0), \text{tree}} = -\frac{\pi^2}{G_F^2 M_W^2 V_{tb}^* V_{ts}} \frac{m_\mu \tan \beta}{2v} R_M g_{sb} = \frac{g_{sb}^*}{g_{bs}} C_S^{(0)}, \quad (6.10)$$
where
\[
R_M = \frac{M^2_h \sin^2(\beta - \alpha) + M^2_{H^0} \cos^2(\beta - \alpha)}{M^2_h M^2_{H^0}}
\]  
(6.11)
contains the dependence on the neutral Higgs-boson masses. The counterterms required
to cure the divergences at one and two loops can be obtained from Eqs. (6.3) and (6.7) by
the simple replacements \( g_{ct} \rightarrow -g_{ct} \) and \( g_{tt} \rightarrow -g_{tt} \). The renormalised Wilson coefficients
\( C_S \) and \( C'_S \) are related to the pseudoscalar ones by
\[
C^{(i)}_S = \frac{R_M}{M^2_{A^0}} C^{(i)}_P, \quad C'^{(i)}_S = -\frac{R_M}{M^2_{A^0}} C'^{(i)}_P.
\]  
(6.12)
Note that there are no QCD corrections to \( C^{(i)}_{S,P} \), since they cancel in the matching
calculation.

7 Phenomenology

In this section we discuss the possible size of \( \mathcal{B}(B_s \rightarrow \mu^+ \mu^-) \) in our 2HDM under the
constraint that other \( b \rightarrow s \) processes comply with the data. We include the tree-level
contributions from diagrams with flavour-changing down-type couplings (cf. Fig. 4), as
well as the SM results and the leading quadratic tan \( \beta \) contributions in the type-II 2HDM
to which the additional diagrams of order tan \( 3\beta \) discussed in the previous section add as
corrections.

In a generic 2HDM the tree-level couplings \( g_{bs}^\pm \) will drastically increase the branching
ratio for \( B_s \rightarrow \mu^+ \mu^- \) due to the missing loop suppression. In our model the spurion expan-
sion suppresses \( g_{bs}^\pm \) in a controlled way, but still permits large enough contributions to get
phenomenologically interesting effects in \( B_s \rightarrow \mu^+ \mu^- \): Even rather small up-type couplings
\( g_{ct} \) significantly modify the Wilson coefficients \( C^{(i)}_P \) and \( C'^{(i)}_S \), as they feature a CKM factor
\( V_{cs} \) instead of \( V_{ts} \). In the following, we will restrict ourselves to the experimentally favoured
scenario [67, 68] of aligned Higgs doublets, in which \( \sin(\beta - \alpha) \approx 1 \). For the numerical
analysis, we will set \( \sin(\beta - \alpha) = 1 \), and therefore have \( R_M = M^2_{H^0} \). In this case, the
Higgs mass eigenstates \( h^0 \) and \( H^0 \) coincide with \( \phi^0 \) and \( -\phi^0' \), respectively, and only the
latter possesses non-SM-like couplings to fermions. This reduces the number of relevant
non-Yukawa-type parameters of the extended Higgs sector to four, namely \( \tan \beta, M_{H^+}, M_{A^0} \)
and \( M_{\phi^0'} = M_{H^0} \).

7.1 Constraints from \( b \rightarrow s\gamma \) decays

An important constraint on the magnitude of flavour-changing Yukawa couplings in the
up-type quark sector arises from the inclusive rare decays \( B \rightarrow X_s \gamma \). This process is
mediated at the quark level by \( b \rightarrow s\gamma \) through a top quark loop with a charged \( W \) boson
in the Standard Model and receives additional contributions through charged-Higgs boson
diagrams in the 2HDM, see Fig. 6. In order to eliminate the dependence on \( V_{cb} \approx -V_{ts} \),
one traditionally works with the quantity
\[
R_\gamma \equiv \frac{\mathcal{B}(b \rightarrow s\gamma) + \mathcal{B}(b \rightarrow d\gamma)}{\mathcal{B}(b \rightarrow d\nu)}.
\]  
(7.1)
Figure 6. Sample Feynman diagram for the rare decay $b \to s\gamma$ at one loop in the 2HDM. The cross indicates a chirality flip $t_L \to t_R$.

Note that in the SM and the type-II 2HDM the branching ratio of $b \to d\gamma$ is much smaller than that of $b \to s\gamma$.

In the type-II 2HDM, the contribution of the charged Higgs diagrams to the decay rate is positive, moving the theoretical prediction for the branching ratio away from the experimental value averaged in [16] to

$$R_{\gamma,\text{exp}} = (3.22 \pm 0.15) \cdot 10^{-3},$$  
(7.2)

where a lower cutoff of $E_0 \geq 1.6$ GeV has been put on the photon energy. The practical independence of $R_{\gamma}$ of $\tan \beta$ in the largest part of the parameter space in the type-II 2HDM allowed for the extraction of a lower limit on the mass of the charged Higgs boson in [16], see section 5. In the general 2HDM, where the factor $\tan \beta$ from the $btH^-$ vertex need not be cancelled by a factor $\cot \beta$ from the $stH^-$ vertex, the quantity $R_{\gamma}$ depends on $\tan \beta$. The combination of the $\bar{t}_L b_R H^+$ and $\bar{s}_L t_R H^-$ Yukawa couplings arising in the process is then given by

$$\left( m_b \frac{\tan \beta}{v} V_{tb} \right) \left( \frac{m_t V_{ts}^*}{v \tan \beta} + V_{ts}^* g_t + V_{cs} V_{cd} \right) = \frac{m_b m_t V_{tb} V_{ts}^*}{v^2} \left( 1 + g_{st}^{\text{eff}} \right),$$  
(7.3)

where we have defined the short-hand notation

$$g_{st}^{\text{eff}} = \frac{v \tan \beta}{m_t} \left( \frac{V_{cs}^*}{V_{ts}} + g_t \right).$$  
(7.4)

Note that $g_{st}^{\text{eff}}$ carries a factor of $\tan \beta$. We stress that the limit $g_{st}^{\text{eff}} = 0$ corresponds to the type-II 2HDM, while the case $g_{st}^{\text{eff}} = -1$ is the Standard Model limit. In order to constrain our new flavour-changing couplings, we use the results from [69] and [16] with this trivial change of the $\bar{s}_L t_R H^-$ Yukawa coupling.

For large enough values of $M_{H^\pm}$, the central value of $R_{\gamma}$ is approximately given (at
\[ \mu = \overline{m}_t (\overline{m}_t) \] by

\[
R_\gamma \approx 10^{-4} \left\{ 33.10 |_{\text{SM}} + \left( 1 + \text{Re} g_{\text{eff}}^{\text{st}} \right) \left[ r_H \left( -48.93 - 47.60 \log r_H - 0.99 (\log r_H)^2 \right) - 0.15 (\log r_H)^3 + 4.71 \text{Li}_2 \left( 1 - \frac{1}{r_H} \right) \right] + r_H^2 \left( -53.82 - 98.18 \log r_H + 4.79 \text{Li}_2 \left( 1 - \frac{1}{r_H} \right) \right) + r_H^3 \left( -56.04 - 150.43 \log r_H + 3.17 \text{Li}_2 \left( 1 - \frac{1}{r_H} \right) \right) \right\}, \quad (7.5)
\]

which agrees with the exact result within 1% in the complete subdomain of \((M_{H^\pm}, \text{Re} g_{\text{eff}}^{\text{st}}) \in [500 \text{ GeV}, \infty) \times [-5, 5]\) in which \(R_\gamma \) lies within the band allowed by the experimental and theoretical uncertainties (see below). The approximate formula in Eq. (7.5) only includes the interference of the new-physics contribution with the SM result and neglects the squared new-physics contribution. In deriving Eq. (7.5) we have used Eq. (10) of Ref. [70]. We adopt the estimate of the theoretical uncertainty of about 6.73% given in [16], consisting of individual uncertainties of 5% (non-perturbative), 1.5% (parametric), 3% (higher-order), and 3% (interpolation in the charm quark mass \(m_c\)). In Fig. 7, we illustrate the ratio \(R_\gamma\) in the \((M_{H^\pm}, \text{Re} g_{\text{eff}}^{\text{st}})\) plane. The thick dashed line corresponds to the central experimental value in Eq. (7.2) and \(R_{\gamma, \exp} \pm \Delta_{\exp+\text{th}}\), where \(\Delta_{\exp+\text{th}} = 2\sigma_{\exp} + \delta_{\text{th}}\) is the sum of the experimental 2\(\sigma\) uncertainty intervals and the theoretical uncertainty of 6.73%. For small values of \(M_{H^\pm}\), the allowed range of \(g_{\text{eff}}^{\text{st}}\) is tightly constrained around \(g_{\text{eff}}^{\text{st}} = -1\), due to the closeness of the Standard Model prediction and the experimental central value. At larger \(M_{H^\pm}\), a significantly wider range of flavour-changing Yukawa couplings is allowed. From \(R_\gamma\) we derive \(M_{H^\pm}\)-dependent upper and lower bounds on \(\text{Re} (g_{\text{eff}}^{\text{st}})\) which we will use in order to constrain the real part of the flavour-changing up-type couplings appearing in \(B_s \to \mu^+ \mu^-\).

### 7.2 Higgs searches

Searches for heavy Higgs bosons at the LHC put powerful lower limits on the masses of new Higgs particles, but these depend on the Yukawa sector of the considered 2HDM. For the case of the type-II model (or ramifications of it) these searches already exclude a significant portion of the \(M_{A^0} - \tan \beta\) plane at present. In Fig. 8, we show a recent collection of exclusion limits obtained through various different searches by the ATLAS experiment [66] in a modification of the type-II model. These limits imply that large values of \(\tan \beta\) can only be realised if at the same time the additional Higgs bosons are quite heavy, \(M_{A^0} \gtrsim 1.5\text{ TeV}\).

It should be noted that for heavy \(M_{A^0}\) these bounds also approximately apply for \(M_{H^+}\) and \(M_{H^0}\), since the masses become degenerate in the heavy-Higgs limit (for a thorough analysis of the allowed mass splittings see [71]). Note that the bounds from neutral Higgs searches are more constraining than those for \(H^+\) searches [65]. The most stringent constraints are from final states with \(\tau\)’s and also apply to our lepton Yukawa Lagrangian in
Figure 7. The ratio $R_\gamma$ as a function of the charged Higgs boson mass $M_{H^\pm}$ and $g_{M}^{\text{eff}}$. The dashed lines correspond to the experimental central value and the $\pm 2\sigma$ intervals, to which we have also added the theoretical uncertainties.

Eq. (3.18) which we have chosen of type-II. (However, the choice of the $\tau$ Yukawa couplings is of no relevance for the phenomenology of the $b \to s$ FCNC processes discussed in this paper.) The presence of the additional couplings $g_{jik}^{\mu}$ will increase some branching ratios at the expense of those of decays into $\tau$’s, so that these bounds can be somewhat weakened, but the general trend remains valid. Our scenarios discussed below comply with the ATLAS bounds.

7.3 $B_s - \bar{B}_s$ mixing

The effective $s_L b_R A^0$ and $s_L b_R H^0$ vertices are the sum of the tree-level couplings $\propto g_{sb}$ and the loop contributions involving vertex and self-energy diagrams $\propto g_{ct} V_{tb} V_{cs}^* + g_{tt} V_{tb} V_{ts}^*$. $C_P$
and $C_S$ are proportional to this effective vertex, which is therefore the relevant quantity constrained by $\mathcal{B}(B_s \to \mu^+\mu^-)$. Now the $B_s - \bar{B}_s$ mixing amplitude depends quadratically on this effective vertex, while both quantities drop quadratically with $M_{A^0}$ and $M_{H^0}$, so that the quantities give complementary information on the parameter space. $B_s - \bar{B}_s$ mixing is mediated in the Standard Model by the $\Delta B = 2$ operator $Q_{SLL} = \bar{b}_{R} s_{L} (\bar{b}_{L} s_{R} A_{0}) + \bar{s}_{R} b_{L} (\bar{s}_{L} A_{0}) + \bar{s}_{R} b_{L} (\bar{s}_{L} H_{0})$, which violates hypercharge by two units of the Higgs hypercharge and therefore gives rise to a strong suppression due to the small splitting of Higgs masses in the large-mass limit. However, considering the ATLAS constraints implying large masses $M_{A^0,H^0}$, $C_{SLL} \propto 1/M_{A^0}^2 - 1/M_{H^0}^2$ is heavily suppressed due to the small splitting of Higgs masses in the large-mass limit, and $C_{SLR}$ becomes relevant. This feature results from the fact that $Q_{SLL}$ violates hypercharge by two units of the Higgs hypercharge and the coefficient $C_{SLL}$ is therefore suppressed by a factor
of $v^2/M_A^2$ compared to $C_{SLR}$ multiplying $Q_{SLR}$ which conserves hypercharge and SU(2). As a consequence, $C_{SLR}$ is more important than $C_{SLL}$. This feature has been widely studied in the context of the effective 2HDM emerging from integrating out superpartners in the MSSM [23–25, 27].

In the following we correlate $\mathcal{B}(B_s \to \mu^+\mu^-)$ with $\mathcal{B}(B \to X_s\gamma)$ and the $B_s - \bar{B}_s$ oscillation frequency $\Delta M_{B_s}$, which is proportional to the magnitude of the $B_s - \bar{B}_s$ mixing amplitude. Only the effective $s_L b_R A^0$ and $\bar{s}_L b_R H^0$ vertices are physical, by e.g. changing the renormalisation condition for $g_{sb}$ we can shift pieces between $g_{sb}$ and the renormalised loop. For simplicity, we set the tree-value of $g_{sb}$ to zero, i.e. consider the case that this coupling is only generated radiatively. The only non-trivial Yukawa structure entering the considered observables is then $g_{st}^{s\mu}$.

In Fig. 9 and Fig. 10 we illustrate the dependence of the branching ratio $\mathcal{B}(B_s \to \mu^+\mu^-)$ on the flavour-changing Yukawa couplings for some exemplary numerical values. We choose to show our results separately for the LHCb [54, 55] and CMS [56] measurements, which lie on different sides of the SM prediction calculated with the $|V_{cb}|$ from inclusive decays. The interval allowed on the horizontal axis (the real part $\text{Re}(g_{st}^{s\mu})$) is for each choice of Higgs masses determined by the range allowed by $b \to s\gamma$. Recall that $g_{st}^{s\mu}$ carries a factor of $\tan\beta$, which needs to be taken into account if the bounds on $g_{st}^{s\mu}$ were to be converted into direct bounds on $g_{ct}$ and $g_{ht}$. A priori generic $\lesssim \mathcal{O}(0.1)$ values of $g_{ct}$ could make $g_{st}^{s\mu}$ in Eq. (7.4) as large as $\mathcal{O}(50)$. For the considered Higgs masses such large values of $|g_{st}^{s\mu}|$ are forbidden by $b \to s\gamma$ and the range for $\text{Im}(g_{st}^{s\mu})$ shown on the $y$ axis in plots (a) to (d) only serves the purpose to show the constraint from $\mathcal{B}(B_s \to \mu^+\mu^-)$. Low values for Higgs masses enforce small values for $\tan\beta$ from the LHC searches, but for these scenarios $b \to s\gamma$ forbids any measurable effect in $\mathcal{B}(B_s \to \mu^+\mu^-)$. This situation changes if one considers large values for $\tan\beta$ and the Higgs masses, because $\mathcal{B}(B_s \to \mu^+\mu^-)$ grows faster with $\tan\beta$ than $\mathcal{B}(B \to X_s\gamma)$, see plots (e) and (f). We find that in the considered scenarios the bounds from $\mathcal{B}(B \to X_s\gamma)$ are stronger than those from $\Delta M_{B_s}$, which we always find in the band allowed by the current theoretical uncertainty. This situation changes if we go to even larger Higgs masses, permitting larger values of $|g_{st}^{s\mu}|$ in $\mathcal{B}(B \to X_s\gamma)$. The quadratic dependence of $\Delta M_{B_s}$ on $g_{st}^{s\mu}$ makes $\Delta M_{B_s}$ a good probe of the parameter region in which both the Higgs masses and $g_{st}^{s\mu}$ are large.

We do not study the case of sizable imaginary parts of the new FCNC couplings here. These imaginary parts impact CP asymmetries such as $A_{CP}^{m_A}(B_s \to J/\psi\phi)$, which will be investigated in a follow-up paper. All numerical SM input parameters are given in Tab. 1. Note that we do not take into account uncertainties in the input parameters as the dependence of the branching ratio is much weaker than the dependence due to the variation of flavour-changing Yukawa couplings.

We stress here that the presented calculation equally applies to $B_d \to \mu^+\mu^-$ with the change $V_{ts} \to V_{td}$, but this is not true anymore when considering the constraint from $B_d - \bar{B}_d$ mixing because of the additional dependence on the light quark mass. Since $m_d$ is negligibly small, the $B_d - \bar{B}_d$ mixing amplitude becomes insensitive to the effective $bdA^0$ and $bdH^0$ couplings.
Figure 9. Branching ratio of $B_s \rightarrow \mu^+ \mu^-$ for different values of Higgs masses and tan $\beta$. All quantities are evaluated at $\mu = m_t (m_t)$. The red dashed and dotted lines indicate the experimental central value and the 2$\sigma$ uncertainties of LHCb branching ratio measurement [54, 55], respectively. The constraint of $\mathcal{B}(B \rightarrow X_s \gamma)$ on $|\text{Im} g_{st}^{\text{eff}}|$ is not shown.
(a) $M_{H^\pm} = M_{H^0} = M_{A^0} = 600\text{ GeV}$, (b) $M_{H^\pm} = M_{A^0} = 800\text{ GeV}$, $M_{H^0} = 600\text{ GeV}$, tan $\beta = 7$.

(c) $M_{H^\pm} = M_{H^0} = M_{A^0} = 1200\text{ GeV}$, (d) $M_{H^\pm} = 1200\text{ GeV}$, $M_{H^0} = M_{A^0} = 1100\text{ GeV}$, tan $\beta = 12$.

(e) $M_{H^\pm} = M_{H^0} = M_{A^0} = 2000\text{ GeV}$, (f) $M_{H^\pm} = 1950\text{ GeV}$, $M_{H^0} = 2050\text{ GeV}$, $M_{A^0} = 2000\text{ GeV}$, tan $\beta = 60$.

Table 1. Numerical input used for the phenomenological analysis. For the QCD running of the top-quark mass and the renormalisation scale, we have used RunDec [77, 78]. The numerical values of the CKM matrix elements have been taken from the updates provided on the CKMfitter [79] web page. The numerical values of the $B_s$ decay widths have been taken from the online updates provided at the HFLAV web page [58].

8 Summary

We have presented a 2HDM with three flavour-breaking spurions in the quark Yukawa sector. The model contains the established type-I and type-II models as limiting cases and otherwise permits large FCNC couplings in the up-type sector while naturally suppressing FCNC effects in down sector, as required by data. Despite the large number of parameters the model makes characteristic predictions, such as correlations between $b \to s\mu^+\mu^-$, $b \to s\gamma$, and $B_s - \bar{B}_s$ mixing, all of which involve the same combination $g_{\text{eff}}^{st}$ of fundamental parameters. Also all couplings to right-handed down-type quarks are proportional to the quark masses as in the type-II model.

We have studied in detail the rare decay $B_s \to \mu^+\mu^-$, calculated the Wilson coefficients of the effective operators $Q_S$ and $Q_F$, and demonstrated the consistency of the model by showing that the UV counterterms follow the pattern of the spurion expansion. Next we have calculated next-to-leading order (two-loop) QCD corrections to this process to (i) verify that higher-order QCD corrections can be correctly included (e.g. all UV divergences could be renormalised in the usual way plus counterterms for our new couplings) and (ii)
tame the sizable renormalisation-scale dependence of the Yukawa couplings. Then we have studied the phenomenology of an FCNC coupling $g_{ct}$ of the heavy neutral Higgs bosons to top and charm quarks. We have found that —contrary to expectation— the dominant contribution to the loop-induced $s_L b_R A^0$ and $s_L b_R H^0$ couplings do not come from vertex diagrams with the neutral Higgs coupling to the internal top-charm line, but from charged-Higgs couplings which inherit the dependence on $g_{ct}$ through SU(2) symmetry. The corresponding diagram (FCNC self-energy with the neutral Higgs attached to the $b$ line) is enhanced by a factor of $\tan \beta$ compared to the vertex diagram, resulting in a $O(\tan^3 \beta)$ contribution to the $B_s \to \mu^+ \mu^-$ amplitude which is absent in the type-II model. This feature makes $B_s \to \mu^+ \mu^-$ a sensitive probe of the model even for Higgs masses well above the lower bounds found by the LHC experiments. For small Higgs masses, however, $b \to s \gamma$ precludes large effects in $B_s \to \mu^+ \mu^-$. In our model the dominant contribution to $B_s - \bar{B}_s$ mixing is naturally small due to a suppression factor of $m_s m_b / v^2$; nevertheless $B_s - \bar{B}_s$ mixing sets constraints on the parameter space for very large Higgs masses.

Acknowledgments

M.L. would like to thank Florian Herren, Syuhei Iguro, Lucas Kunz and Mustafa Tabet for helpful discussions. The authors are grateful to Matthias Steinhauser for collaboration in an early stage of the project. This research was supported the BMBF grants 05H18VKCC1 and 05H21VKKBA as well as Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) within the Collaborative Research Center Particle Physics Phenomenology after the Higgs Discovery (P3H) (project no. 396021762 – TRR 257). All Feynman diagrams within this paper have been produced using TikZ-FeynHand [80, 81].
